ABSTRACT

Garlic (Allium sativum L.) is the most important species of the Allium genus and an important vegetable crop throughout the world. Garlic is widely used as an obligatory part in many cooked dishes. It is one of the ancient plants playing one of the most important dietary and medicinal roles in human beings for centuries. Garlic possesses many therapeutic properties including antimicrobial, antiviral, antifungal, cardioprotective, neuroprotective, anticarcinogenic, antinutagenic, anti-hypertensive, anti-diabetic and antioxidant. This study has focused on the comparison of the total polyphenols content, the total sulphur content and antioxidant activity of the studied varieties of garlic in the area of Nitra, Slovak Republic. The analyzed samples of garlic were collected at the stage of full maturity. TPC was measured using the spectrophotometric method of Folin-Ciocalteu agents. TPC in studied varieties of garlic were determined in the range 742 mg.kg⁻¹ (Mojmir) to 635 mg.kg⁻¹ (Makoi). The determination of the total sulfur content was based on dry combustion in the presence of oxygen and allows for the quantitative conversion of sulfur to SO₂. Statistically significant highest level of TSC recorded in 0.751% (Mojmir) and the lowest level was in 0.523% (Makoi). Antioxidant activity was determined by the spectrophotometric method using a compound DPPH (2,2-diphenyl-1-picrylhydrazyl). The highest value of AA was measured in Mojmir (17.7%). The lowest level was observed in Makoi (12.4%). In all studied samples of garlic was confirmed by the strong dependence of the total polyphenols content, total sulfur content and antioxidant activity.

Keywords: antioxidant activity, garlic, polyphenols, sulphur compounds

INTRODUCTION

Garlic (Allium sativum L.) botanically a member of the Liliaceae family and Allium genus, is considered to be rich in medicinal properties (Amarakoon and Jayasekara, 2017). Garlic is used in medicines and foodstuff for almost three thousand years as evidenced by ancient writings from China, Egypt, Greece, and India (Cardelle-Cohas et al., 2010). Garlic bulb contains water (65%), carbohydrates (28%), organosulfur compounds (2.3%), proteins (mostly allinase; 2%), amino acids (1.2%) and fiber (1.5%) (Divya et al., 2017). Garlic is a source of various biologically active phytomolecules, including organosulfur compounds, phenolic acids, allyl thiouisulfinates, flavonoids, vitamins and minerals (Chen et al., 2013). Garlic contains minerals like germanium, calcium, copper, iron, potassium, magnesium, selenium and zinc, vitamins A, B, and C, fibre and water (Grebselema and Mebrahun, 2013).

The health property of garlic depends up on the bioactive compounds especially the organosulfur compounds, which are also responsible for the pungent flavor of garlic (Rahman, 2007; Yepe et al., 2005). Garlic contains more than one hundred biologically useful secondary metabolites, which include allin, allinase, allicin, S-allyl cysteine (SAC), diallyldisulphide (DADS), diallyltrisulphide (DATS) and methyl allyl trisulphide. The γ-glutamyl-S-alk(en)yl-L-cysteines are the primary sulfur compounds present in garlic. These active compounds are responsible for protection of tissue from damage and various disorders (Divya et al., 2017). The undamaged bulbs contain allin which will be enzymatically converted to allicin during cutting. Allicin, is the major bioactive compound found in garlic followed by other organosulfur compounds (Amarakoon and Jayasekara, 2017).

The health properties of garlic depend on its bioactive compounds and especially on phenolic compounds, which have interesting pharmacological properties, are present in relatively high amounts (Chen et al., 2013). Phenolic compounds are large groups of secondary metabolites that are able to neutralize or quench the free radicals. Flavonoids and their derivatives are the largest group of polyphenols found in plants (Hounsoue et al., 2009). The content of phenolic compounds in garlic thus varies greatly with genetic, agronomic, and environmental factors, and it is well known that cultivar is the primary factor that determines this variation (Chen et al., 2013).

The antioxidants are substances that delays, prevents or removes oxidative damage to a target molecule. Antioxidants are an inhibitor of the process of oxidation, even at relatively small concentration and thus have diverse physiological role in the body. A variety of free radical scavenging antioxidants is found in dietary sources like fruits, vegetables and tea (Yadav et al., 2016). The antioxidant potential of garlic in vivo and in vitro has been proved. Biochemical studies have demonstrated that garlic acts as antioxidant to protect cells against reactive oxygen species (ROS) (Chung, 2006).

Garlic show a wide range of beneficial health effects to treat various infectious diseases, non-communicable diseases as well as metabolic and genetic disorders. An overview is provided on the numerous clinical and experimental investigations done on the reduction of LDL cholesterol level, cardiovascular disease, blood glucose levels by garlic derivative compounds (Amarakoon and Jayasekara, 2017). The therapeutic potential of this plant product inhibits invasion of carcinoma, provides cardiovascular protection, lowering of cholesterol and blood pressure, anti-platelet activities, and thromboxane formation. In addition the biological activities of garlic include antibacterial, antithrombotic, antioxidant, immunomodulatory, anti-diabetic and modulation of drug metabolism. The other proposed uses of garlic include hepatoprotection, anesthetic, anti-inflammation, antifungal and wound healing (Divya et al., 2017). This study was designed to determine the variability in the content of total polyphenols, sulfur compounds and antioxidant capacity in variety of garlic cultivars.
MATERIAL AND METHODS

The local climate conditions

This study was performed in area of Nitra, Slovak Republic. Nitra is situated on the south-western Slovakia in the area of Podunajská lowland. Nitra belongs to warmer and dry areas with mild winters in Slovakia. The average annual rainfall is 550 – 600 mm and the average annual temperature is 9 - 10 °C. Nitra have very good natural and climatic conditions for crop growth, without any adverse effects.

Sample preparation

Garlic was divided into cloves and homogenized. 25 g of homogenized garlic were extracted in 50 ml of 80% ethanol (Sigma – Aldrich Co, USA), which were shaken (shaker GFL 3006, 125 rpm) for sixteen hours. Samples were kept at laboratory room temperature in dark conditions until the analysis. Each determination was carried out in six replications.

Determination of total polyphenols

Total polyphenols content (TPC) was determined by the method according to Lachman et al. (2003). It is expressed as mg of gallic acid (Merck group, Germany) equivalent per kg of fresh matter. Total polyphenols content was determined using the Folin-Ciocalteu reagent (Merck group, Germany). 2.5 ml of Folin-Ciocalteu reagent was added to 100 ml extract to volumetric flask. The content was mixed. After 3 minutes, 5 ml 20% solution of sodium carbonate (Merck group, Germany) was added. Then the volume was adjusted to 50 ml with distilled water. After 2 hours, the samples were centrifuged (centrifuges CENTURION XVI.I (Statpoint Technologies, Inc., USA) x 100 minutes in the same way as DPPH solution. The percentage of inhibition shows how antioxidant compounds are able to remove DPPH radical at the given period of time.

Statistical analysis

Results were statistically evaluated by Analysis of Variance by one-way ANOVA (Multiple Range Tests) was performed, and the data were considered to be significantly different when p < 0.05 using statistical software Statgraphics Centurion XVII (Statpoint Technologies, The Plains, Virginia, USA) and a correlation analysis (Microsoft Excel, Redmonde, Washington, USA) was used.

RESULTS AND DISCUSSION

The content of total polyphenols, total sulfur compounds and antioxidant activity in the studied varieties of garlic (Mojmír, Záhorský, Anton and Makoi) from area Nitra are presented in Table 3. The content of total polyphenols in the studied varieties is varied from 635.1 ± 6.1 mg.kg⁻¹ to 742.0 ± 5.2 mg.kg⁻¹. The highest level of total polyphenols was measured in Mojmír. In variety Makoi was detected the lowest value of total polyphenols content. In variety of Mojmír average level of TPC is 1.17-times higher than in variety Makoi. The studied varieties of garlic according to determined values of TPC can be arranged in following order: Mojmír > Anton > Záhorský > Makoi. Mahmutovic et al. (2009) indicated the total polyphenols content in the range 488 mg.kg⁻¹ to 800 mg.kg⁻¹, Bayili et al. (2011) measured TPC in garlic 741 mg.kg⁻¹, which is consistent with our results. Chekki et al. (2014) measured the lower level of TPC - 436 mg.kg⁻¹ also Zarakova et al. (2014) – 450 mg.kg⁻¹, in comparison with this study. The total sulfur content in the studied varieties of garlic ranges from 0.524 ± 0.016% to 0.751 ± 0.018% (Table 3). The highest level of TPC was measured in Mojmír. The lowest level of TSC was observed in Makoi. In variety Mojmír average level of TSC is 1.43-times higher than in Makoi. The determined quantity of total sulfur content in the samples can be arranged in the following order: Mojmír > Anton > Záhorský > Makoi. Benkeblia and Lanzotti (2007) indicated that the value of TSC in studied varieties of garlic move in wide range from 0.23% to 0.56%, Mills et al. (2005) determined the total sulfur content with a value of up to 1%. Muradic et al. (2010), measured the value TSC of garlic 0.63%, which good correlate with the results of this work.

The value of antioxidant activity in the studied varieties of garlic ranges from 12.4 ± 0.3% to 17.7 ± 0.4% (Table 3). The statistically significant highest level of AA was measured in variety Mojmír. The lowest level of AA was detected in variety Makoi. The average level of AA in variety Mojmír is 1.43-times higher than in variety Makoi. According to determined values of AA the studied varieties of garlic can be arranged in the following order: Mojmír > Anton > Záhorský > Makoi. Sayin and Alkan (2015) indicate that the values of antioxidant activity is 16%, which good correlate with the results of this work. Rai et al. (2015) reported even a higher value of antioxidant activity in garlic 21.5%. The lower value of antioxidant activity in garlic 7% was measured by Choi et al. (2014).

1 Limit value for aqua regia – Law No. 220/2004
The relations among the total polyphenols content, total sulfur content and the antioxidant activity in studied varieties of garlic (Mojmír, Záhorský, Anton and Makoi) were evaluated (Figure 1-8). The coefficient of correlation ($r = 0.8831 - 0.9940$) confirmed strong dependency between TPC, TSC and AA. The results are in good agreement with the findings of Ramkissoon et al. (2012) and Chen et al. (2013) confirmed correlations between total polyphenols content and antioxidant activity in garlic and other vegetable. Mahmutovic et al. (2014), who indicated correlations between total polyphenols content, total sulfur content and antioxidant activity in garlic.

Multiple Range Tests, Method: 95.0 percent LSD, Different letters (a, b, c and d) between the factors show statistically significant differences ($p < 0.05$).

The relations among the total polyphenols content, total sulfur content and the antioxidant activity in studied varieties of garlic (Mojmír, Záhorský, Anton and Makoi) were evaluated (Figure 1-8). The coefficient of correlation ($r = 0.8831 - 0.9940$) confirmed strong dependency between TPC, TSC and AA. The results are in good agreement with the findings of Ramkissoon et al. (2012) and Chen et al. (2013) confirmed correlations between total polyphenols content and antioxidant activity in garlic and other vegetable. Mahmutovic et al. (2014), who indicated correlations between total polyphenols content, total sulfur content and antioxidant activity in garlic.
CONCLUSION

The total polyphenols content, total sulfur content and antioxidant activity in studied varieties of garlic (Mojmír, Anton, Záhorský and Makoi), grown in locality Nitra were comparable with literature. The statistically significant differences in the monitored parameters were detected in the studied varieties of garlic. The highest value of total sulfur content, total polyphenols content and antioxidant activity was measured in variety Mojmír. The lowest value of the monitored indicators was determined in variety Makoi. The coefficient of correlation confirmed strong dependency between the total sulfur content, total polyphenols content and antioxidant activity. Health benefits of garlic depend on its content of biologically-active compounds (polyphenols, sulfur compounds and antioxidant active ingredient), which differs between cultivars.
